ABSTRACT

The search for improved performance of U.S. Navy ships has led to more complex propulsion systems consisting of multiple, interacting inputs. Classical control theory does not effectively exploit these interactions. Modern control theory provides a systematic method of dealing with multiple interacting inputs to achieve improved system performance. One of the most highly developed modern control techniques is the linear quadratic regulator (LQR) method. Essential to the application of this method is the formulation of a state space description of the plant. In this paper a nonlinear dynamic propulsion system model is developed from experimental data and used to formulate a state space model. (Thesis)

I. INTRODUCTION

The search for improved performance of U.S. Navy ships has led to increasingly complex marine propulsion systems. Controllable inputs to this system now include fuel flow rate, engine inlet guide vane and stator vane position, bleed air selection, and propeller pitch angle. Current control strategies applied to these propulsion plants, and classical control techniques in general, do not take into account the interaction between these inputs. In contrast, modern control techniques (MCT) provide a systematic method to achieve improved system performance when dealing with multiple, interacting inputs. Specifically, modern control theory methods provide the following benefits not found in classical control methods applied to multiple input, multiple output (MIMO) systems:

- (1) Effective treatment of coupled input interactions to improve performance,
- (2) Rigorous treatment of stability questions,
- (3) Systematic control design which reduce iteration and the need for extensive intuition and experience in the control design process.

The most extensive application of modern control theory to date is the F100 Turbofan Multivariable Control Synthesis Program, sponsored by the Air Force Aero Propulsion Lab and Nasa Lewis Research Center. [Ref. 1: p. 43]. The results of this program demonstrated that modern control theory techniques provide an orderly, effective, systematic approach to controller design for multiple, interacting input systems.

Current work at the Naval Postgraduate School, Monterey, is aimed at investigating the application of modern control techniques to U.S. Navy ship propulsion plants. The initial phase of this effort involves the application of modern control techniques to a low power gas turbine test

facility located at the school. In the context of this effort the goals of this thesis were:

- (1) Development of an accurate digital computer model of the propulsion test facility which includes all significant plant nonlinearities and dynamic effects.
- (2) Develop a linear (state-space) model of the propulsion plant.

The nonlinear model is a valuable tool in controller design. First, it provides a means to test control strategies without risking damage to the actual plant. Second, it provides a cost effective alternative to extensive controller tests. Finally, in this work the nonlinear model provided the basis from which a linear (state space) model was derived.

The state space model of the propulsion plant is essential for future controller design work at NPS using the linear quadratic regulator (LQR) technique, which is the most highly developed modern control method. [Ref. 2: p. 653].

II. OVERVIEW

This thesis is organized into eight chapters. In the following chapter a description of the test facility at the Naval Postgraduate School (NPS) is given. Also in that chapter, a conceptual model of the plant is developed. The plant is first divided into functional components. The significant plant dynamics are identified, and the number of plant components is reduced so that only the degree of complexity necessary to represent the significant plant processes is retained. Finally, the component interactions are defined by identifying component inputs and outputs. The component interactions link the components together and form a basis for quantitative modeling of the plant.

In Chapter 4 quantitative (versus conceptual) component modeling is described. Using experimental data, the input/output relations for each component (as defined in the previous chapter) are constructed in equation form.

In Chapter 5 the individual component equations are joined together to form a steady state plant model.

In Chapter 6 the differential equations governing the plant dynamics (identified in Chapter 3) are introduced into the steady state model. In this way a nonlinear dynamic plant model is developed.

In Chapter 7 the state space model is derived from the nonlinear dynamic model.

Chapter 8 contains conclusions and recommendations for further work.

III. PLANT DESCRIPTION/CONCEPTUAL MODELING

A. PLANT DESCRIPTION

The test facility (hereafter referred to as 'the plant') consists of a Boeing model 502-6A 175 horsepower gas turbine engine and a Clayton 17-300 water dynamometer. Figure 3.1 is a schematic of the test facility.

The gas turbine can be subdivided into the gas generator section and the power take-off section. The gas generator section consists of a single stage centrifugal compressor, a dual can combustor, an accessory drive section, and a single-stage axial flow high pressure turbine (HPT). The power take-off section consists of a single-stage axial flow free power turbine (FPT). Fuel enters the combustor via the fuel control, which consists of a flyball governor and an acceleration limiter. The fuel control setting is adjusted by an electric-motor driven control lever. The hot gases drive the high pressure turbine. The high pressure turbine, in turn, drives the compressor and accessory drive section. The accessory drive section extracts power from the high pressure turbine to drive the fuel pump and governor, the oil pump, and a tachometer generator. The free power turbine extracts energy from the hot gas stream and drives the dynamometer. There is no mechanical connection between the high pressure turbine and the free power turbine.

The water dynamometer acts as a power absorption unit. The power turbine torque and speed are adjusted by varying the amount of water in the dynamometer. This is analogous to changing the pitch on a controllable pitch propeller. Water enters and leaves the dynamometer via electric motor driven load and unload valves.

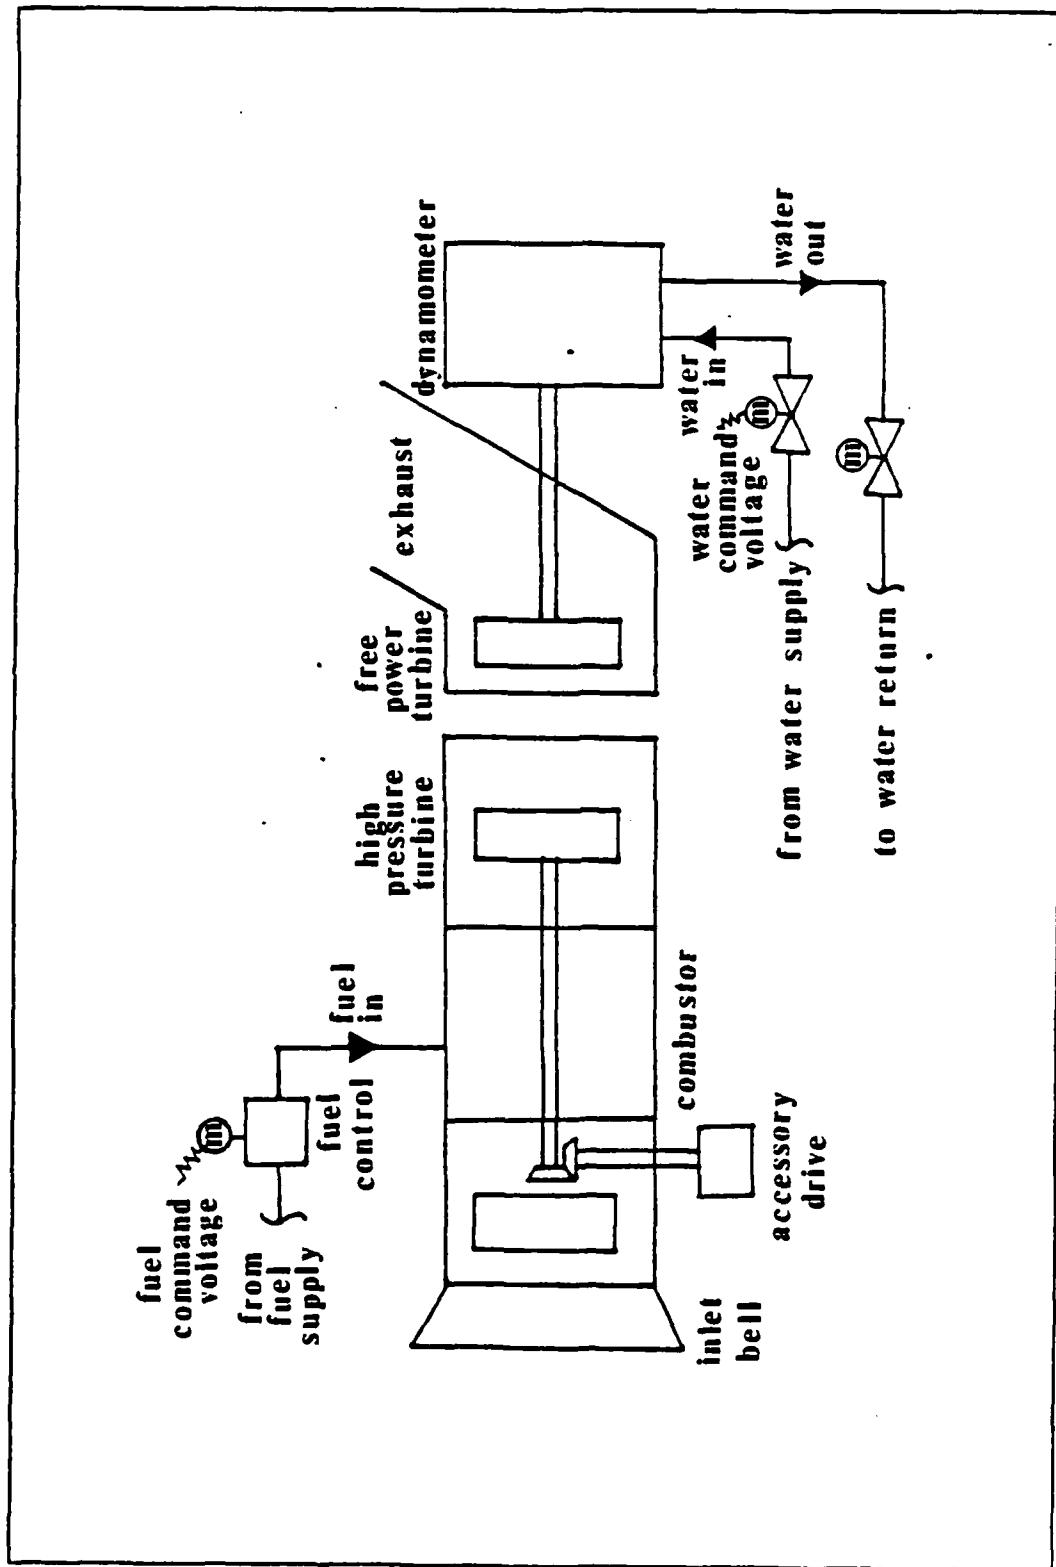

Figure 3.1 NPS Marine Propulsion Test Facility

B. THE CONCEPTUAL PLANT MODEL

In formulating a conceptual plant model the following issues must be addressed:

- definition of plant boundaries,
- identification of significant plant dynamics,
- extent to which the plant must be divided into components and how the components selected, and
- definition of component inputs and outputs.

These issues are discussed below.

1. Plant Boundaries

Selection of plant boundaries is important since this selection determines the plant inputs. Because the long range goal of this project is the implementation of an improved control system, the existing fuel control was excluded from the plant model. The plant boundary was located downstream of the existing fuel control, and actual fuel flow to the combustor (versus fuel command voltage) was established as one plant input.

A model of the dynamometer was developed in earlier work by Johnson [Ref. 3]. This model accurately describes the behavior of the dynamometer during loading conditions (water addition to the dynamometer), but is less accurate during unloading conditions. The source of the dynamometer model inaccuracies is thought to involve the unload valve behavior. In order to avoid introduction of the unload valve inaccuracies into the propulsion model developed in this study, the load and unload valves were placed outside the plant boundaries. Thus, actual water to and from the dynamometer (versus water command voltage) was established as the second plant input.

2. Plant Components

Breaking the plant into components facilitates the identification of causal relationships and plant dynamics. Further, the plant components provide the foundation of plant model development.

The selection of components is a cut and try process. A first cut at component identification is shown in Figure 3.2.

This selection was based on a functional basis and assumptions about the significant processes occurring within the plant. The minimum number of components necessary to account for these processes is sought. If the resulting model is insufficiently accurate, then some significant process has either been overlooked or improperly described. In either case, the selection of components must be reevaluated.

3. Significant Dynamics

Paramount to model accuracy is the identification of significant plant dynamics. Fluid momentum and compressibility, heat transfer, energy storage, rotor inertia, and combustion effects are all possibilities. However, dynamic effects can only be considered significant in the practical sense if their time constants are neither much shorter nor extremely longer than those for the controller actuators and sensors. Previous work by Szuch [Ref. 4:p. 243] in the area of aircraft gas turbine controls indicated that fluid momentum, compressibility, and energy storage dynamics occur too rapidly to be controlled, while heat transfer dynamics occur too slowly to be important in the control problem.

The importance of combustion dynamics deserves special discussion. Szuch [Ref. 4:p. 243] and DeHoff [Ref. 5:p. 274] concluded that combustion dynamics were of too high frequency to be important in controls considerations. In contrast, Rubis [Ref. 6:p. 56] discusses significant transient effects associated with engine torque development in response to fuel flowrate changes. These effects could be due in part to combustion related delays. In the present work combustion effects were initially neglected. The resulting model produced excessive

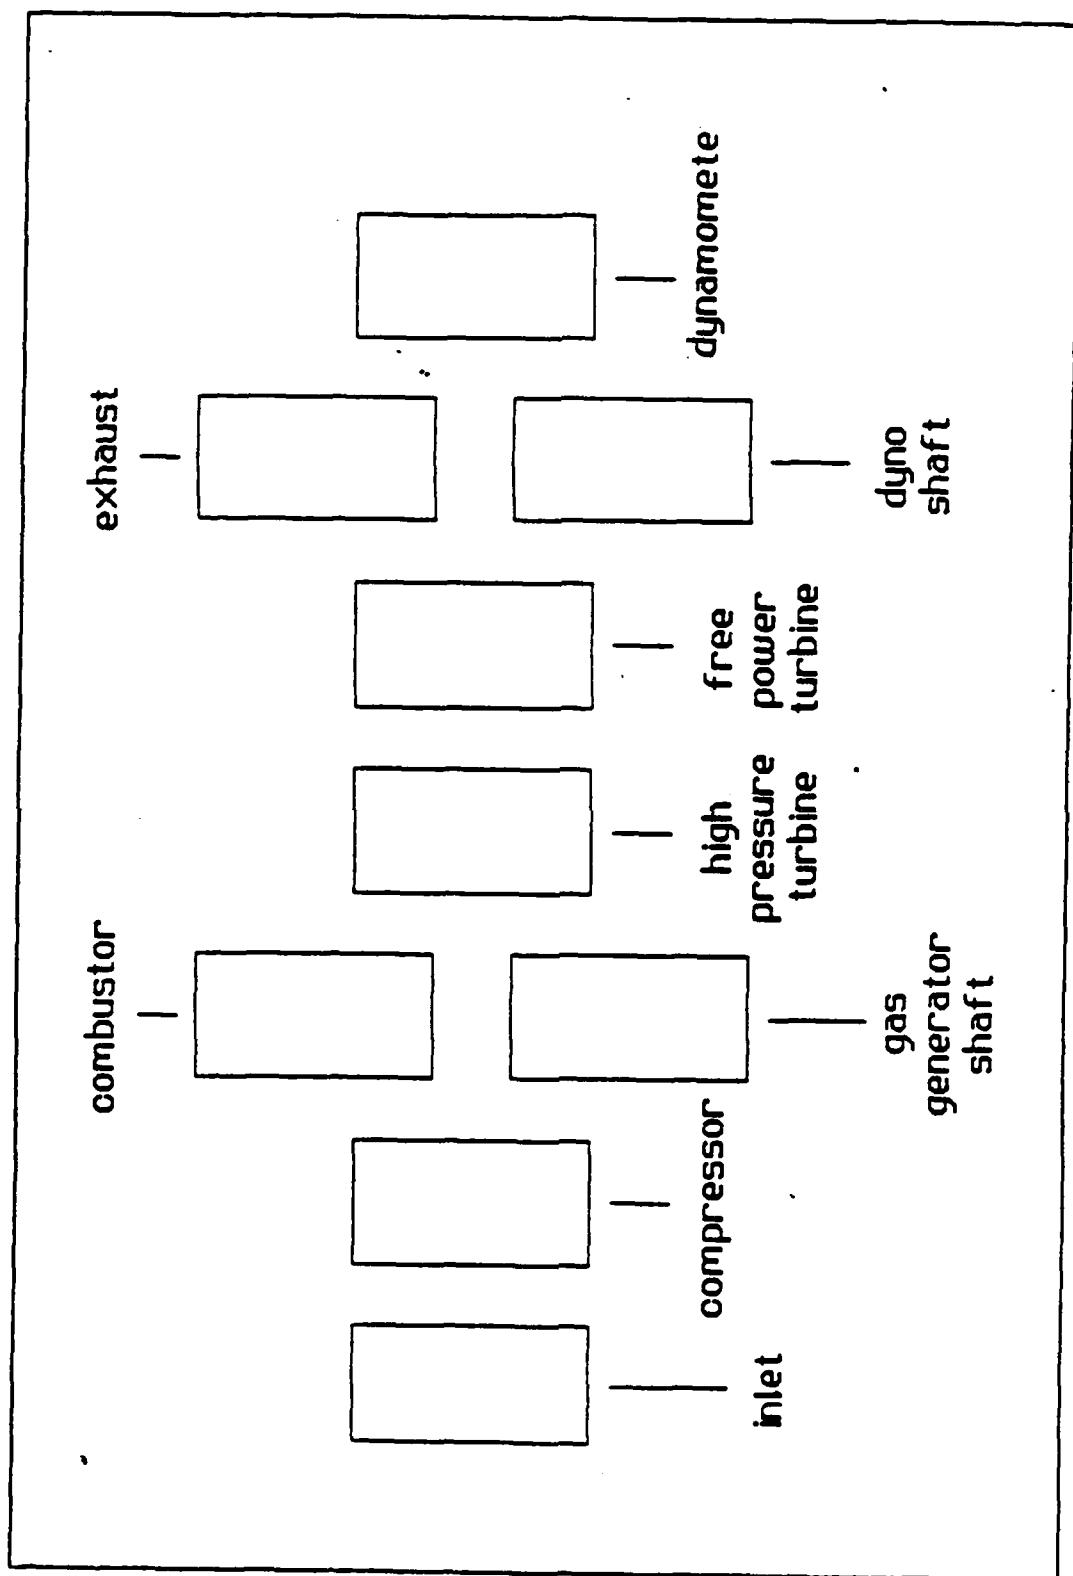

Figure 3.2 Propulsion Plant Components

accelerations when compared to experimental data. When combustion effects were modeled as a fuel energy lag accurate results were achieved. This fuel energy lag represents the delay between the time when the chemical energy in the fuel passes through the fuel nozzles and the time when the mechanical energy is realized at the high pressure turbine.

In addition to the fuel energy lag, the most significant plant dynamics are the rotor inertia effects. Thus, the equations governing the plant dynamic behavior are:

$$\dot{N}_G = (Q_H - Q_C - Q_A - Q_{FRG}) / J_G$$

$$\dot{N}_S = (Q_F - Q_D - Q_{FRD}) / J_D$$

$$E/M_f = 1/(t_S + 1)$$

Where \dot{N}_G = gas generator acceleration,
 \dot{N}_S = free power turbine acceleration,
 J_G = gas generator inertia,
 J_D = combined free power turbine and dynamometer inertia,
 Q_H = high pressure turbine torque,
 Q_C = compressor torque,
 Q_A = accessory drive torque,
 Q_{FRG} = gas generator frictional torque,
 Q_F = free power turbine torque,
 Q_D = dynamometer torque,
 Q_{FRD} = combined free power turbine and dynamometer frictional torque,
 M_f = measured fuel flowrate at the fuel nozzles,
 E = mechanical energy applied at the high pressure turbine,
 t = time constant associated with the combustion process.

In this study the auxiliary torque (QD) and gas generator frictional torque (QFRG) were lumped into the compressor torque (QD). Also, the dynamometer/power turbine frictional torque (QFRD) was lumped into the dynamometer torque (QD). Having made these simplifications the governing dynamic equations become:

$$\dot{N}_G = (Q_H - Q_C)/J_G \quad (3.1)$$

$$\dot{N}_S = (Q_E - Q_D)/J_D \quad (3.2)$$

$$M_f/E = 1/(t_S + 1) \quad (3.3)$$

4. Model Simplification

Once the significant dynamic effects are determined and the governing equations identified, the plant model may be simplified by reducing the number of components. As noted in the overview, it will be necessary during the model development to define the input/output relationships for each component in equation form. If the dynamic effects can be lumped into isolated components, then the input/output equations for these components are already known; they are the governing differential equations for the plant dynamics. Further, if the dynamic effects are lumped into isolated components, then the input/output equations for the remaining components can be obtained from steady state data since these components are assumed to contain no dynamic effects. This approach was applied to the current modeling problem and the reduced component model of Figure 3.3 was produced.

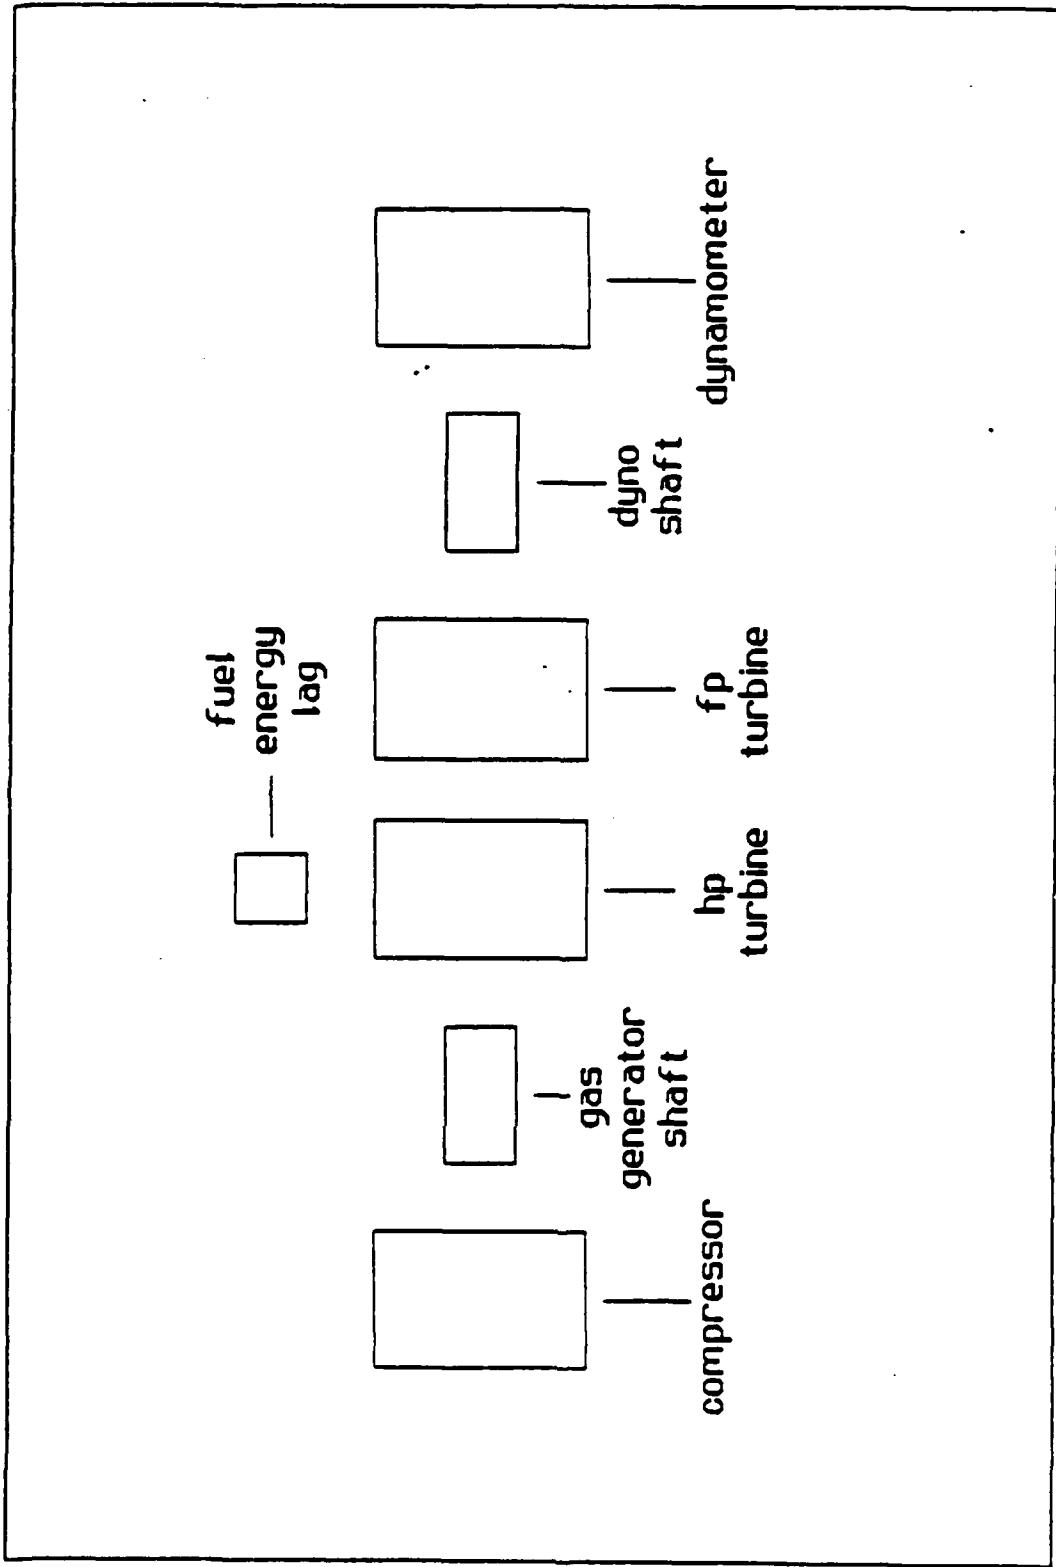

Figure 3.3 Reduced Component Model

In this work two dynamic effects are the accelerations of the gas generator and the power turbine/dynamometer. By lumping the entire gas generator inertia into the gas generator shaft, the gas generator acceleration dynamics were isolated to that component. Similarly, the power turbine/dynamometer dynamics were lumped into the power turbine/dynamometer shaft. The third dynamic effect, the fuel combustion dynamics, was lumped into a single component, a first order lag between the fuel flowrate input and the high pressure turbine.

Since no dynamic effects were considered to occur in the inlet bell or exhaust duct, these components were combined with the compressor and free power turbine, respectively.

5. Component Inputs/Outputs

The next step in formulating the conceptual model is determining the inputs and outputs of each component. Multiport analysis using signal pairs at "ports" of power transfer is one useful method for studying component interaction.

At the mechanical-rotational port (gas generator and power turbine/dynamometer shafts) the signal pair is torque, Q , and rotational speed, N , as shown in Figure 3.4. More difficult to represent is the thermofluid power transfer between the compressor, high pressure turbine, and free power turbine. If the fluid flow were incompressible the port would be represented by a pressure-volume flowrate signal pair as shown in Figure 3.5.

However, this simple representation is not adequate for the case of compressible flow since it does not account for thermal energy transfer via the fluid internal energy. One could represent this port as shown in Figure 3.6 where $U = M * u$, with M the mass flowrate and u the fluid specific internal energy.

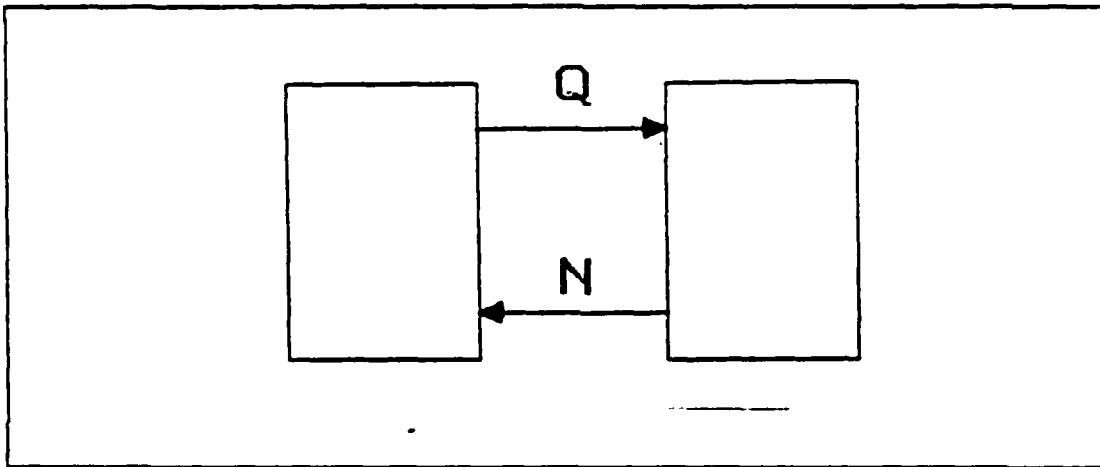

Figure 3.4 Mechanical-Rotational Port

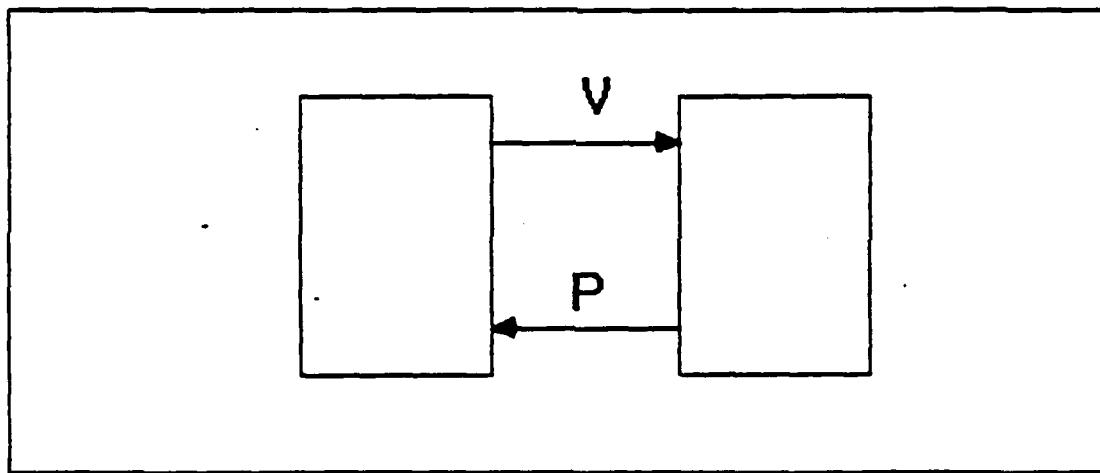

Figure 3.5 Incompressible Fluid Port

Representing internal energy as the product of specific heat (C_v) and temperature, the port could be rewritten as shown in Figure 3.7.

One might now attempt to combine effects and describe the complete thermofluid power transfer as shown in Figure 3.8.

However, since the variables P, V, M , and T are related through the equations of state, it is redundant to measure all four in the modeling process.

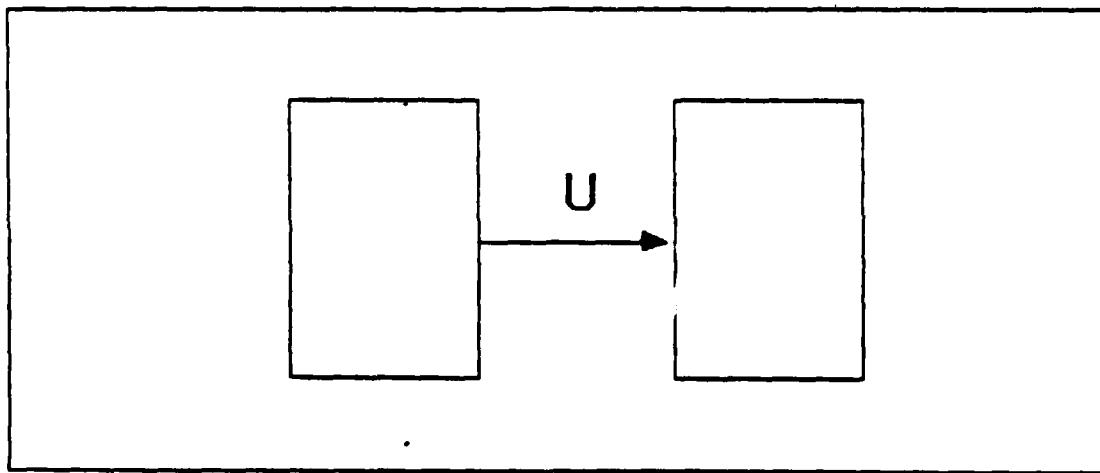

Figure 3.6 Thermal Port

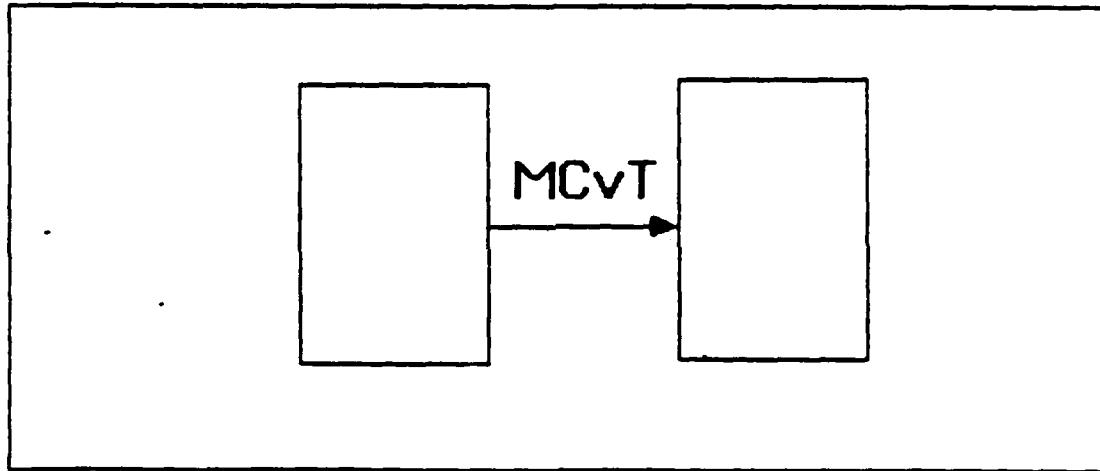

Figure 3.7 Alternate Thermal Port

In considering which variable to eliminate it should be noted that since the direction of mass flow and volume flow must be the same, and since temperature is "carried along" with the mass flow, these three variables have the same signal flow direction. Thus, elimination of the pressure variable was considered unwise since this would essentially eliminate the two-way component interaction. Elimination of temperature from the set of independent

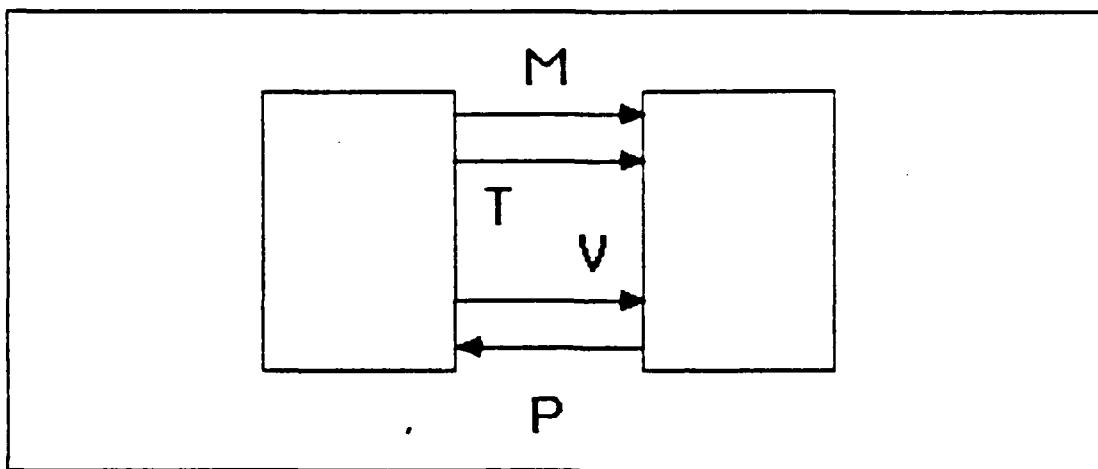

Figure 3.8 Combined Port

variables was considered a poor choice due to its ease of measurement relative to either mass or volume flowrate. Finally, since mass flowrate is conserved while volume flowrate is not, and since this conservation might lead to simplification in future measurements and calculations, it was decided that volume flowrate, V , would be eliminated. The resulting power port is shown in Figure 3.9.

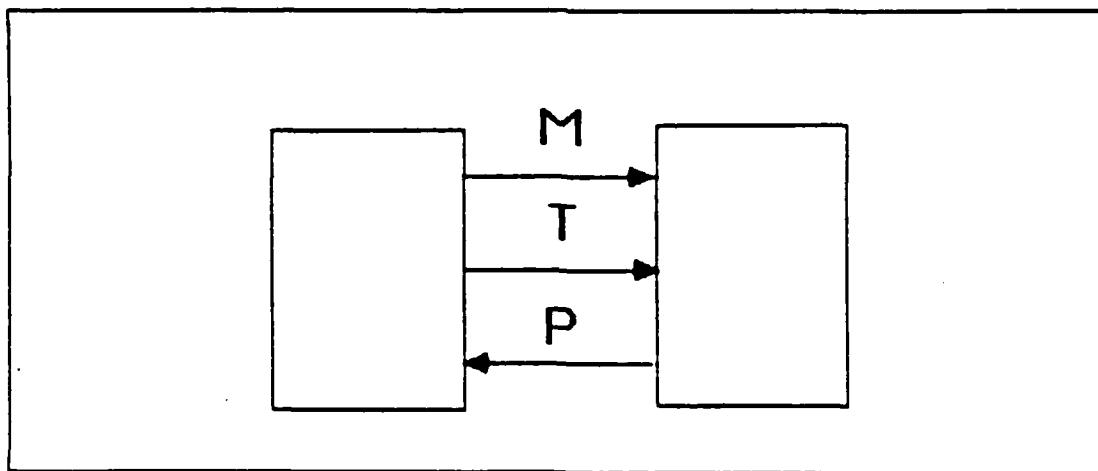

Figure 3.9 Thermodynamic Power Port

Using this concept of the thermodynamic power port the complete multiport diagram was constructed as shown in Figure 3.10. Note that variable ambient conditions were eliminated as system inputs by using corrected variables, a commonly employed technique in gas turbine analysis.

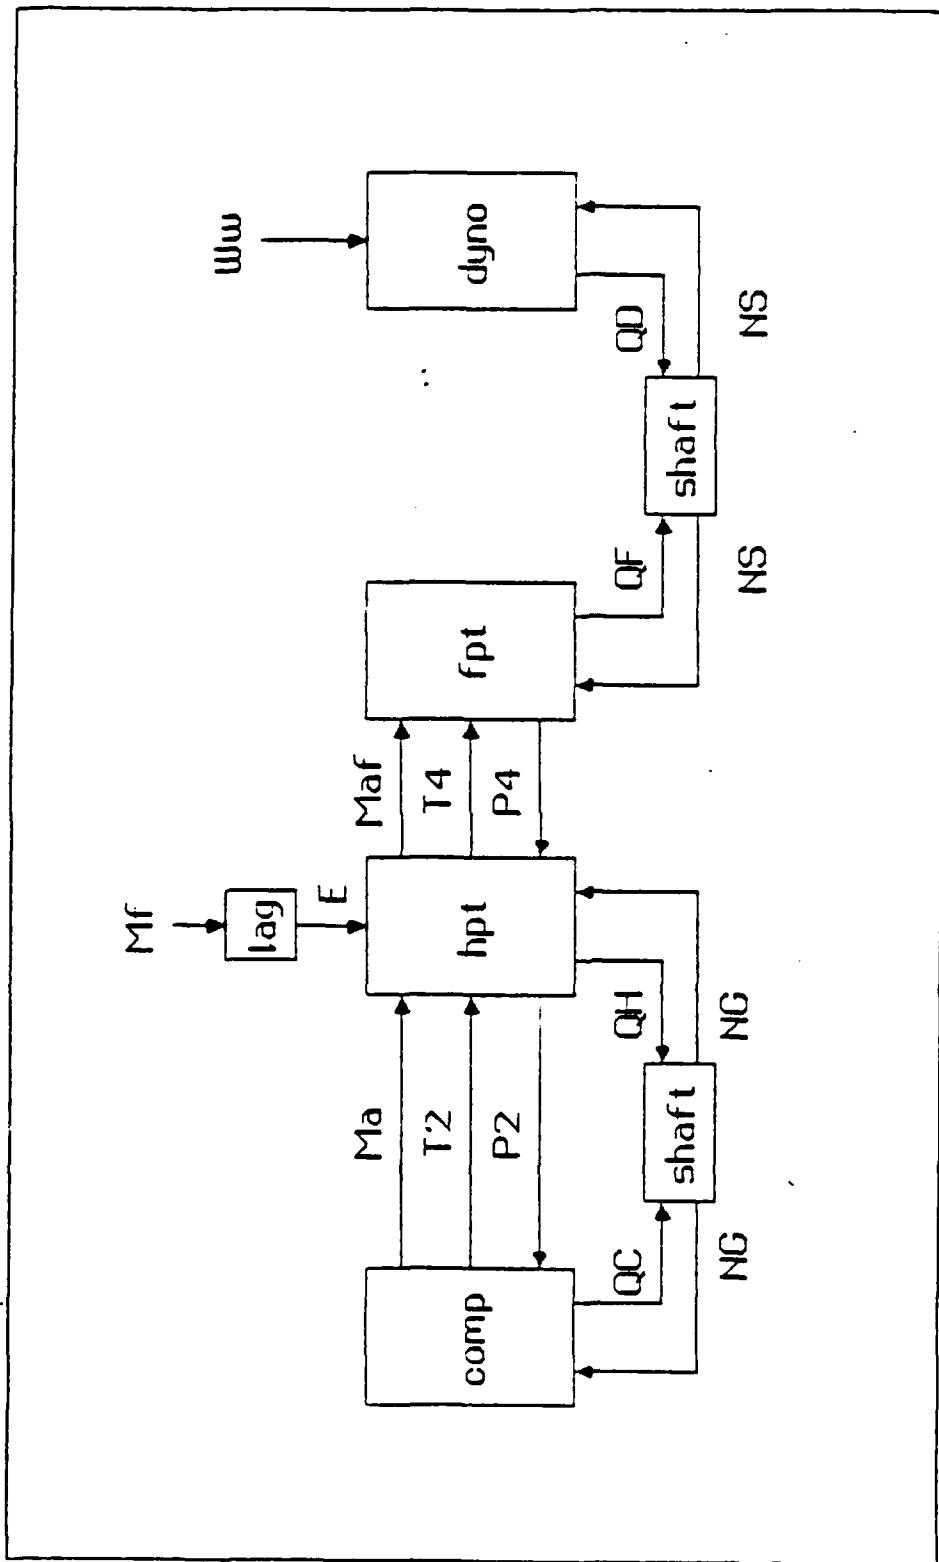

Figure 3.10 Complete Multiport Diagram

IV. QUANTITATIVE COMPONENT MODELING

From the multiport diagram of the previous chapter the component input/output relationships are identified. The next step in the modeling process is to obtain quantitative expressions for these relationships. In this model we have assumed that the gas generator and power turbine/dynamometer shafts, and the fuel energy lag contain the plant dynamic effects. The quantitative relation for these components is the governing differential equations 3.1 , 3.2 and 3.3. Further, since it has been assumed that the remaining components contain no significant dynamic effect, the input/output equations for these components can be obtained from steady state data. The following describes how these equations were obtained.

A. DATA ACQUISITION

The gas turbine and dynamometer is instrumented as indicated in Table 1. The data acquisition system is controlled by an HP-85 personal computer. Temperature, speeds, and torques are taken using an HP-3497A Data Acquisition/Control Unit. Pressure readings are taken using a Pressure Systems DPT-6400. Fuel flowrate is obtained by the operator from two rotometers and entered interactively or from a turbine flowmeter. An HP-82902M flexible disk drive provides program/data storage capability. A Digital DECWRITER IV printer provides hard copy output.

Data was taken at 93 operating points as indicated in Table 2. These points were selected to provide full coverage of the plant operating envelope. At each operating point temperature, speed, and torque values were sampled 30 times and averaged. Pressure values were sampled 8 times and averaged. A copy of the acquisition program is included as Appendix A.

TABLE 1

| Fuel Flowrate | MF | 1 Turbine Flowmeter |

B. DATA REDUCTION

Data reduction took place in two phases. In the first phase average values, generator torque, air mass flowrate, and corrected values were computed. These calculations are part of the data acquisition program (Appendix A).

In the second phase, curve fits were obtained for the input/output relations of each turbine component using the method of least squares [Ref. 7:p. 153] The program which performed the least squares fit is included as Appendix B. Using this program, three types of curve fit were obtained for each input/output relation. The first is a "complete quadratic" curve fit shown in equation 4.1,

$$Y = C1*X1^2 + C2*X1*X2 + C3*X2^2 + C4*X1 + C5*X2 + C6 \quad (4.1)$$

where Y = output (dependent) variable,

$X1, X2$ = input (independent) variables,

$C1, C2, C3, C4, C5, C6$, = constant coefficients.

The second type of curve fit obtained was a "reduced quadratic", so called because the cross product terms (ie., $X1*X2$) found in the "complete quadratic" curve fit were excluded. Equation 4.2 is an example of this format.

$$Y = C1*X1^2 + C2*X2^2 + C3*X1 + C4*X2 + C5 \quad (4.2)$$

The third curve fit type was a linear curve fit. Equation 4.3 is an example of this format.

$$Y = C1*X1 + C2*X2 + C3 \quad (4.3)$$

In each case the result of the curve fit program is the coefficients of the curve fit equation. Because the magnitude of some variables is much larger than others (ie., $NG = 30,000$ rpm, $P4 = 17$ psia) it was necessary to scale the

variables to prevent algorithmic singularities during the least squares solution. This was accomplished by dividing each variable by a scaling factor. The scaling factors, shown in table 3, were selected so that each variable had a range of 0.0 to 1.0 when scaled.

TABLE 3
SCALING FACTORS

| Variable | Scaling Factor |
|--|----------------|
| Gas Generator Speed, NG | 36,000 rpm. |
| Compressor Torque, Qc | 130 ft. lb. |
| Air Mass Flowrate, Ma | 13,000 lb/hr. |
| Compressor Discharge Temperature, T2 | 800 deg. R. |
| Compressor Discharge Pressure, P2 | 43.0 psia. |
| Fuel Mass Flowrate, Mf | 240 lb/hr. |
| High Pressure Turbine Torque, QH | 130 ft. lb. |
| Combined Air/Fuel Mass Flowrate, Maf | 13,000 lb/hr. |
| High Pressure Turbine Discharge Temp., T4 | 1800 deg. R. |
| High Pressure Turbine Discharge Press., P4 | 20.0 psia. |
| Dynamometer Speed, NS | 3,000 rpm. |
| Free Power Turbine Torque, QF | 480 ft. lb. |

V. STEADY STATE PLANT MODEL

A. STEADY STATE MODEL ALGORITHM

With the input/output component relations defined in equation form the next step was to link these relations together to form a steady state plant model. Figure 5.1 presents the flowchart describing the steady plant state model algorithm. In this algorithm the program user inputs the gas generator and dynamometer speeds at which the plant parameters are to be evaluated. The program makes an initial guess at the steady state fuel flowrate, M_f . A guess is also made for the compressor and high pressure turbine discharge pressures, P_2 and P_4 . The program uses these assumed values to calculate the compressor and high pressure turbine outputs. The computed compressor discharge pressure is compared with the assumed value. If the difference between assumed and computed value exceeds the specified tolerance, the value of P_2 is updated. Otherwise, the power turbine outputs are calculated and the computed high pressure turbine discharge pressure is compared with the assumed value. Convergence within the specified tolerance is again required. If this check is

met the compressor and high pressure turbine torques are compared.

These torques should be equal in steady state. If they are not the assumed value of fuel flowrate is updated and the entire process is repeated. The steady state computer model is included as Appendix C.

B. STEADY STATE MODEL RESULTS

The steady state computer program was tested at various points in the plant operating envelope. The output of the computer model was compared with the raw data for the same

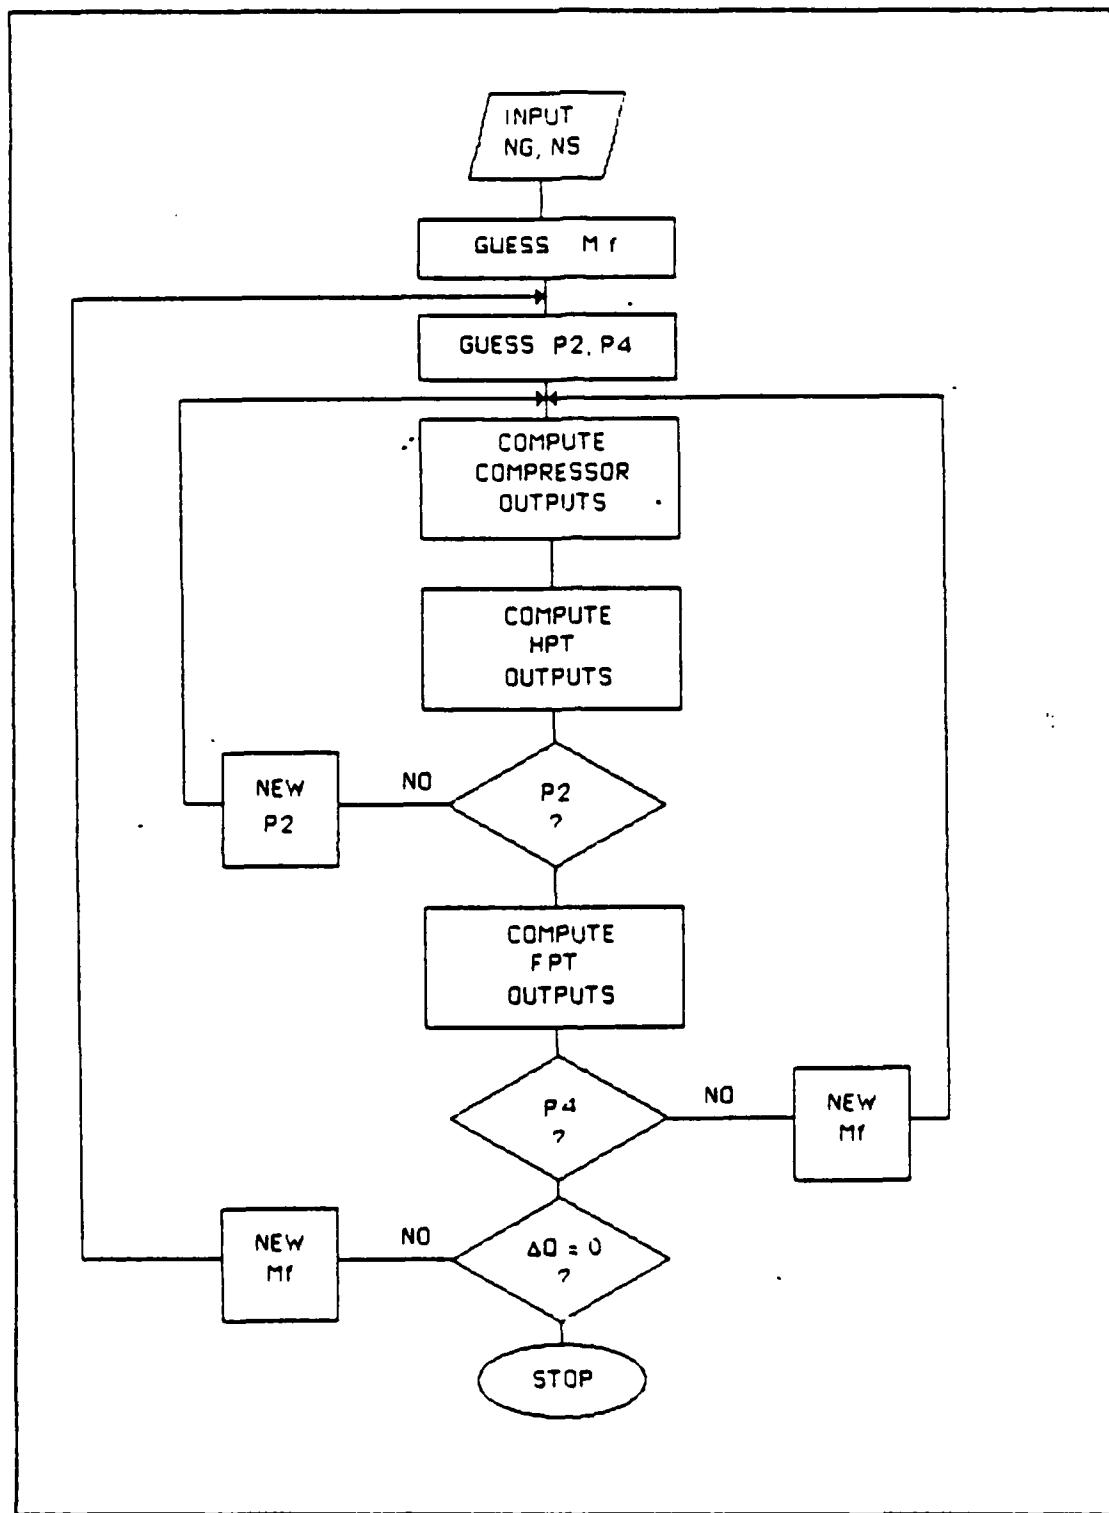

Figure 5.1 Steady State Plant Model Flowchart

operating points. The results showed excellent agreement between the steady state model and the raw data at most operating points. The only exception to this was at extremely high gas generator speeds. A typical comparison is shown in Table 4.

As indicated by the flowchart of Figure 5.1, at any given gas generator speed (NG) and dynamometer speed (NS) combination, the program must hunt for the fuel flow rate that will produce zero torque differential between the compressor and high pressure turbine. An investigation into the nature of the torque differential as a function of fuel flowrate (at fixed NG and NS) provides some interesting insights into the performance characteristics of the engine. As an example, in Figure 5.2 the torque differential is plotted versus fuel flow for NG = 30,000 rpm and NS = 1,100 rpm.

This plot has several interesting features. First, note that there are two values of fuel flowrate that lead to zero torque differential. This suggests that at a given NG/NS combination there are actually two equilibrium conditions. It is thought that the upper fuel flowrate represents a state of inefficient operation. Whatever the source of the higher fuel flowrate condition, comparison with the raw data indicates that the normal operating mode of the turbine is at the lower fuel flowrate.

A second feature of this curve is the peak torque differential. This peak is considered to be a significant characteristic of the gas generator. It is thought to be indicative of the maximum driving torque difference attainable at the specified NG/NS combination. Thus, if one wishes to accelerate the gas generator quickly, this plot indicates the limits of achievable acceleration as well as the optimal fuel input to achieve the greatest acceleration. Clearly, more fuel does not necessarily lead to greater

TABLE 4
COMPARISON OF STEADY STATE OUTPUT WITH RAW DATA
FOR NG = 25,900 RPM, NS = 970 RPM

| Parameter | Symbol | Steady State Computer Output | Raw Data |
|-------------------------------------|--------|------------------------------|---------------|
| Compressor Torque | QC | 69.8 ft. lb. | 69.4 ft. lb. |
| Compressor Disch. Temp. | T2 | 658 deg. R. | 550 deg. R. |
| High Pressure Turbine Disch. Temp. | T4 | 1354 deg. R. | 1361 deg. R. |
| Compressor Disch. Pressure | P2 | 27.41 psia. | 27.42 psia. |
| High Pressure Turbine Disch. Press. | P4 | 16.36 psia. | 16.36 psia. |
| Free Power Turbine Torque | QF | 151.7 ft. lb. | 150.5 ft. lb. |
| Fuel Flowrate | Mf | 110.8 lb/hr. | 110.3 lb/hr. |
| Air Mass Flowrate | Ma | 8696 lb/hr. | 8742 lb/hr. |

acceleration. In fact, this plot suggests that too large a fuel increase can lead to deceleration. One should note, however, that this condition may be impossible to achieve practically, since it presumes that this large fuel change can be made instantly, without changing the NG/NS combination (ie., a perfect step). The fuel energy lag dynamics seem to exclude this possibility in the current application. Further, the existing fuel control devices on most gas turbine facilities would likely prevent this condition from being observed.

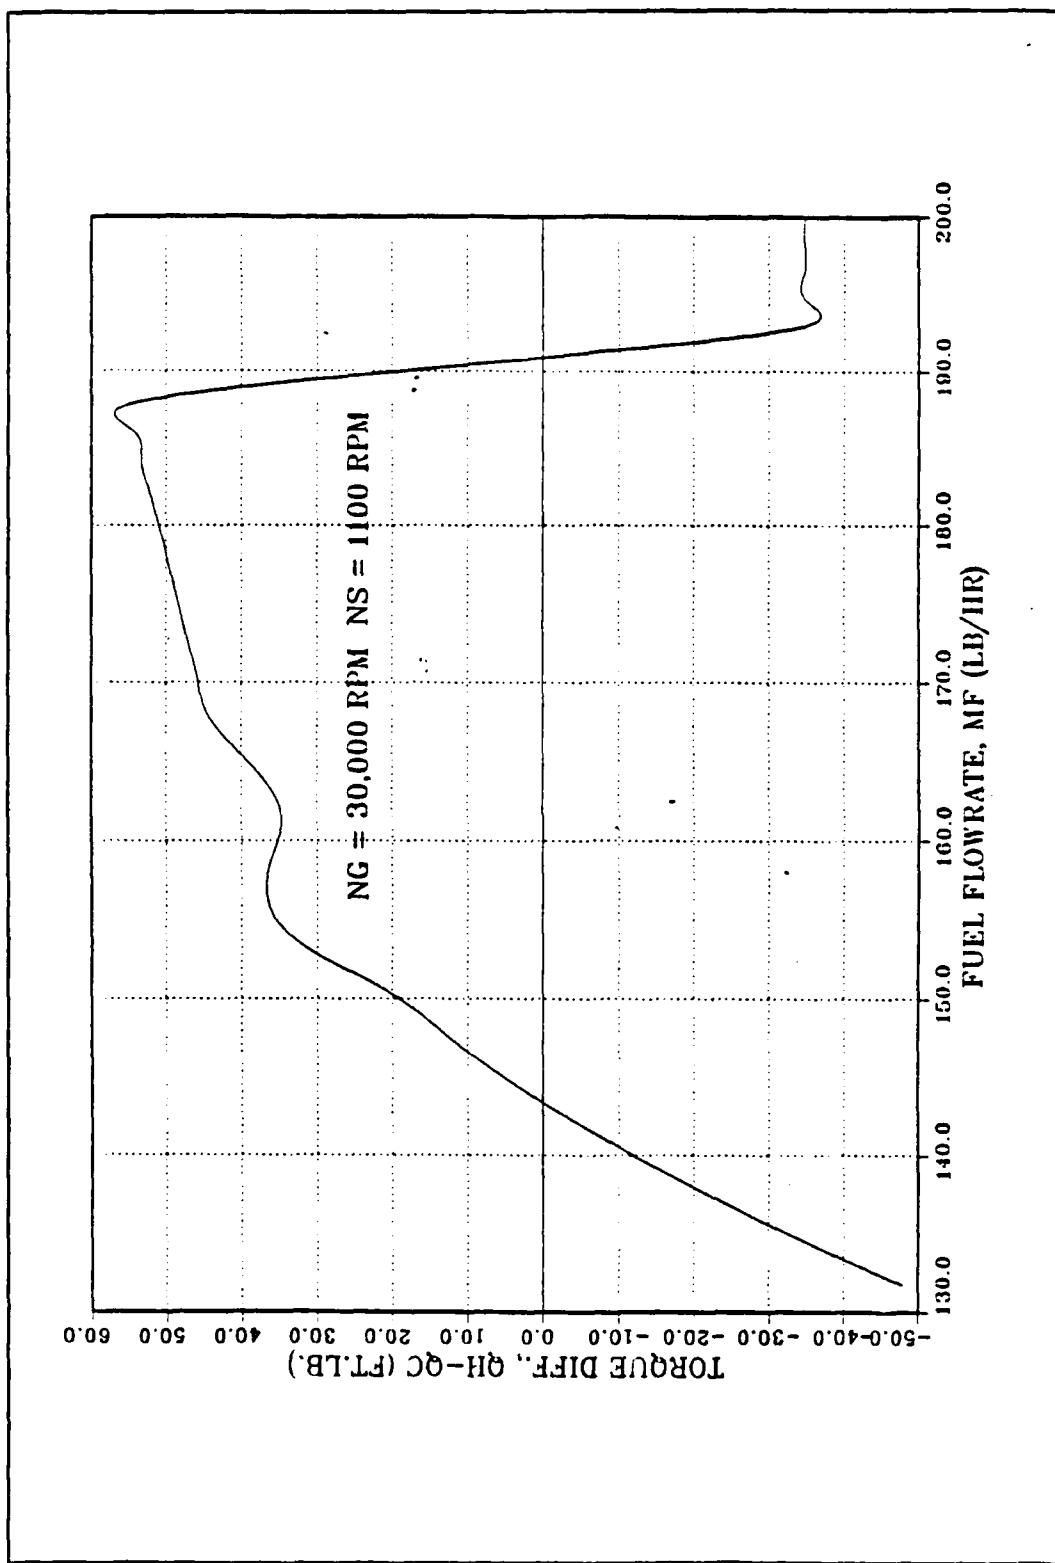

Figure 5.2 Torque Differential .vs. Fuel Flowrate

VI. NONLINEAR DYNAMIC MODEL

The next step was to develop a nonlinear dynamic model by introducing the plant dynamic equations into the steady state model.

In order to implement the governing dynamic equations, the gas generator and power turbine/dynamometer inertias must be known. Johnson [Ref. 3:p. 56] concluded that the combined power turbine/dynamometer inertia (JD) is insensitive to dyno water weight and that a value of $JD = 0.6738 \text{ lb.ft.s}^2$ was valid throughout the operating range.

The following section describes the determination of the gas generator inertia. Subsequently, the development and results of the nonlinear dynamic model is described.

A. GAS GENERATOR INERTIA

The technical manual for the Boeing 502-6A gas turbine engine [Ref. 8:p. 6] lists the gas generator inertia (JG) as 0.11 in.lb.s^2 . However, it was unclear whether this inertia value included the accessory gearbox inertia. Further, the equipment configuration at the NPS test facility is somewhat different than the standard configuration described in the technical manual. Because the gas generator inertia is crucial to accurate dynamic performance prediction, it was desirable to verify the technical manual value experimentally.

In order to experimentally determine the gas generator inertia, the gas generator inlet bell and nose cone was removed. A lever arm was attached to the compressor impeller using existing bolt holes intended for impeller removal. [Ref. 8:p. VII-10]. A spring was attached at each end of the lever arm and secured to the base of the turbine. The resulting experimental set-up is shown in Figure 6.1.

Finally, a potentiometer was attached to the lever arm and aligned with the impeller shaft centerline to permit measurement of impeller angular position.

The lever was deflected and released from rest. Using a strip chart recorder the oscillatory motion of the gas generator was recorded. This procedure was repeated ten times so that good average values could be obtained.

A simplified diagram of the experimental apparatus is given in Figure 6.2, where K is the effective spring constant, J is the total polar mass moment of inertia about the gas generator axis, θ is the angle of rotation, and c is the system damping due to friction. From this simplified diagram the differential equation for viscously damped free vibration is found to be:

$$J \ddot{\theta} + C \dot{\theta} + K \theta = 0 \quad (6.1)$$

The solution to this equation [Ref. 9:p. 25-32] for the underdamped case reveals the frequency of damped oscillation to be:

$$W_d = W_n \sqrt{1 - \zeta^2} \quad (6.2)$$

where W_d = frequency of damped oscillation

W_n = natural frequency

ζ = damping ratio.

Using average values, the frequency of damped oscillation was determined from the strip chart readings to be:

$$W_d = 67.544 \text{ rad/sec}$$

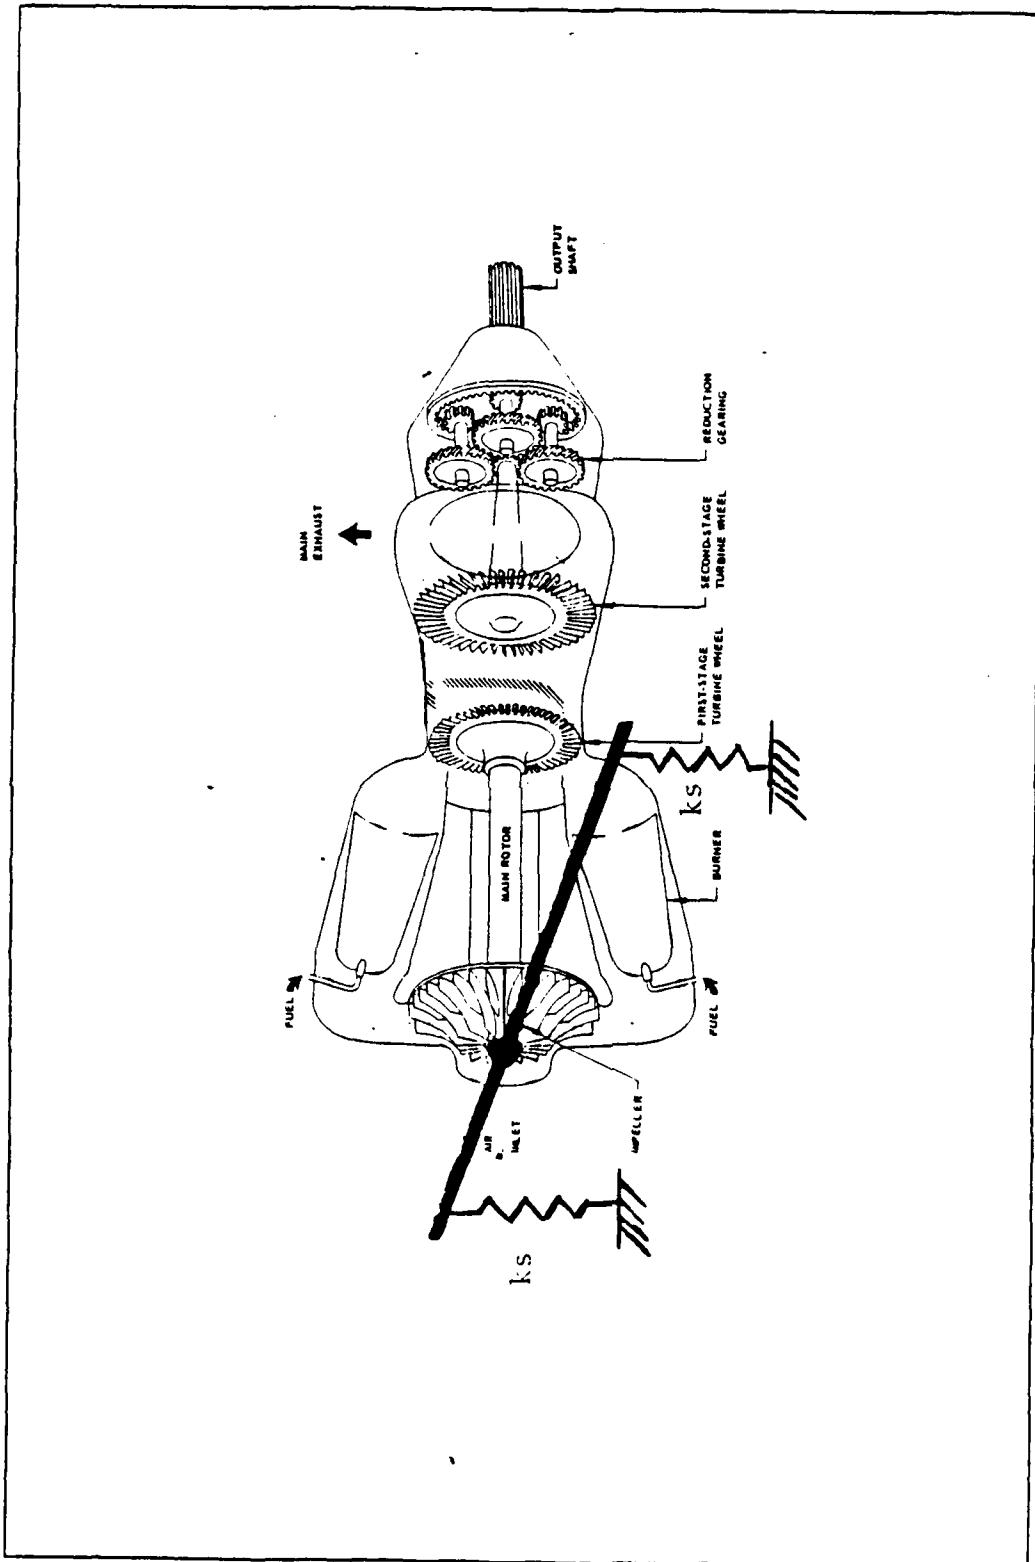

Figure 6.1 Experimental Apparatus for JC Determination
[Ref. 8: fig. 16., p. V-1]

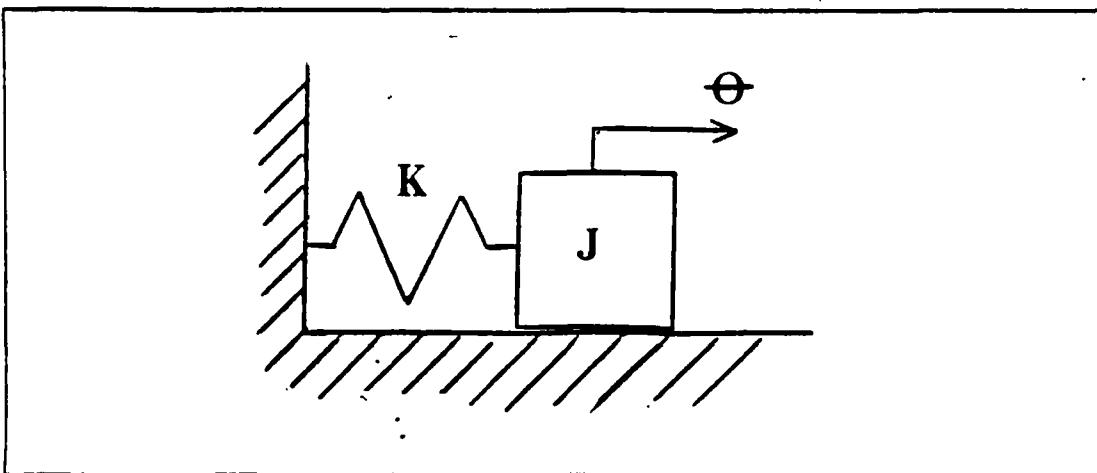

Figure 6.2 Simplified Diagram of Experimental Apparatus

Also from the solution to the free vibration equation, the following relation involving the damping ratio is found:

$$2\pi\zeta/\sqrt{1-\zeta^2} = (1/n)*\ln(X_0/X_n) \quad (6.3)$$

where n = number of elapsed oscillations,
 X_0 = original oscillation amplitude,
 X_n = amplitude after n cycles.

Again using average experimental values, the damping ratio was determined from equation 6.3 to be:

$$\zeta = 0.0325$$

Using the experimentally obtained damping ratio and damped frequency, the natural frequency, ω_n , was determined from equation 6.2 to be:

$$\omega_n = 67.5799 \text{ rad/sec}$$

The natural frequency of the system is also given by:

$$\omega_n = K/J. \quad (6.4)$$

For this system the effective spring constant, K, is:

$$K = 2*ks*R^2 \quad (6.5)$$

where ks = individual spring constant,
 R = distance from gas generator axis to
spring attachment point.

The individual spring constants were experimentally determined to be $ks = 6.891 \text{ lb./in.}$, with $R = 7.0 \text{ inches}$. Solving for the effective spring constant, K , using equation 6.5 the total system inertia, J , was calculated from equation 6.4 to be:

$$J = 0.14786 \text{ in. lb. s}^2$$

The total inertia is equal to the sum of the individual inertia effects of the gas generator rotor (JG), lever arm (JL), and springs (JS):

$$J = JG + JL + JS. \quad (6.6)$$

The lever arm inertia was calculated as:

$$JL = m_l * l^2 / 12 = 0.014457 \text{ in. lb. s}^2 \quad (6.7)$$

where m_l = mass of the lever arm,
 l = length of the lever arm.

The combined inertia of both springs was calculated using Rayleigh's method to be:

$$JS = 2*m_s * R^2 / 3 = 0.01914 \text{ in. lb. s}^2 \quad (6.8)$$

where m_s = mass of each spring.

With the total (J), spring (JS), and lever (JL) inertias determined, the gas generator inertia was found using equation 6.6 to be:

$$JG = 0.1143 \text{ in. lb. s}^2$$

B. NONLINEAR DYNAMIC PROGRAM

The nonlinear dynamic program was formulated using Discrete Simulation Language (DSL). The flowchart describing the dynamic program algorithm is given in Figure 6.3. The user must enter the fuel flowrate and dynamometer water weight as a function of time by editing the program prior to execution. Upon execution of the program the user interactively enters the initial gas generator and dynamometer speeds. The steady state program is then called to determine the equilibrium value of fuel flowrate, M_{fo} , and dynamometer water weight, W_{wo} . A time step is then taken and the new fuel flowrate and water weight is determined. The dynamic effect of the fuel energy lag is then computed. The steady state program is again used to determine the compressor, high pressure turbine, free power turbine, and dynamometer torques (QC , QH , QF , QD respectively). These torques are entered into the dynamic equations describing the gas generator and dynamometer accelerations. Accelerations are integrated to obtain speeds. A check is made to determine if the run time is exceeded. If not, time is again incremented and the loop repeats. A copy of the nonlinear dynamic program is included as Appendix D.

In order to validate the nonlinear dynamic program the propulsion plant test facility was subjected to step changes in commanded fuel flowrate voltage. The resulting fuel flowrate, gas generator speed, and dynamometer speed was

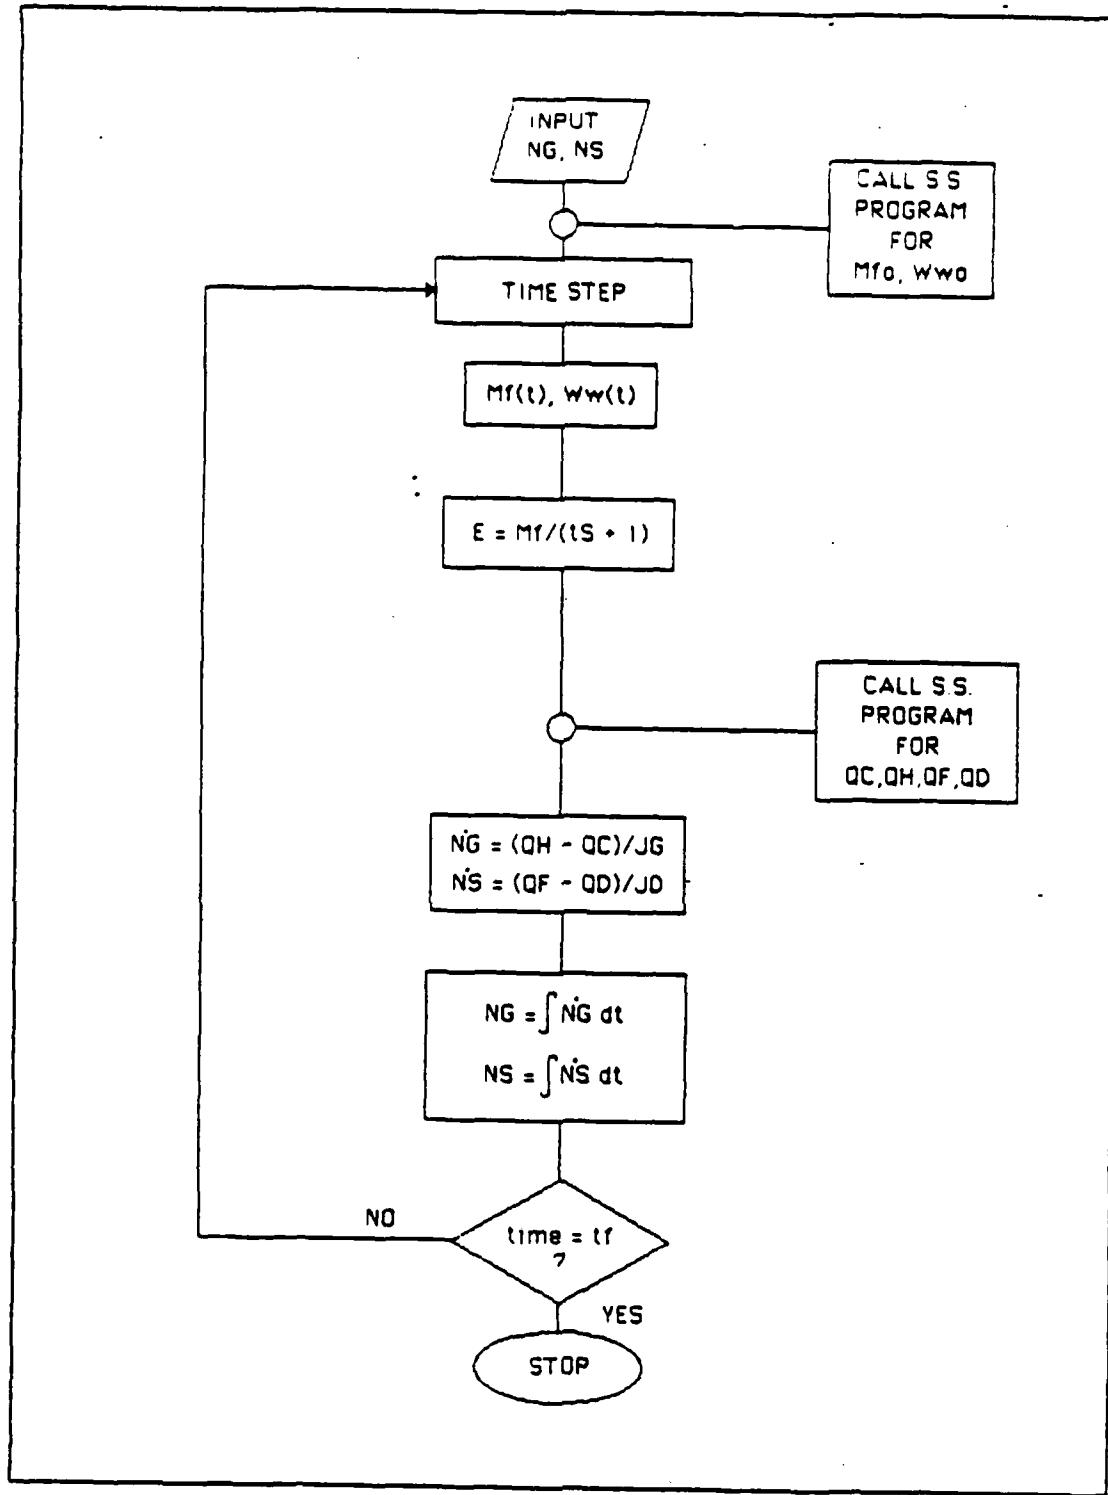

Figure 6.3 Flowchart for Nonlinear Dynamic Program

recorded using a multichannel strip chart. The recorded fuel flowrate versus time was entered into the dynamic program in tabular form and was used to exercise the program. Various acceleration and deceleration tests were conducted. The experimental data were compared with the output of the nonlinear dynamic program. Figures 6.4, 6.5, and 6.6 illustrate the results obtained. In this case an increase in fuel flowrate was applied to accelerate the gas generator from 25,000 to 29,500 rpm and the dynamometer from 960 to 1090 rpm. This represents a large transient, covering nearly one third of the gas generator operating envelope.

Figure 6.4 shows the fuel flowrate transient in response to a step change in commanded fuel flowrate voltage. The discontinuities shown result from the discrete sampling effects of the digital flowmeter, and the unsteady nature of the fuel flow at the location of the flowmeter, just downstream of the fuel control valve. Figures 6.5 and 6.6 show the resulting transients of the gas generator and dynamometer. Experimental data is plotted along with the nonlinear dynamic model results. The results show excellent agreement between the data and the model.

VII. STATE SPACE MODEL

Among modern control theory techniques, the linear quadratic regulator (LQR) method is the most highly developed. This method coordinates multiple inputs simultaneously and provides a straightforward manner in which the feedback gain matrix can be manipulated to achieve the desired system performance. The LQR method calls for the system to be represented in state space form as shown below:

$$\dot{X} = A*X + B*U \quad (7.1)$$

where X = state vector,
 U = input vector,
 A = state coefficient matrix,
 B = input coefficient matrix.

In order to arrive at the state space representation, one must resort to perturbational variables. The excursion of any variable, X , away from its initial condition can be represented by:

$$X = X_0 + x \quad (7.2)$$

where X_0 = the initial value,
 x = dX = the perturbation from
the initial value,
 X = the current value.

Any variable can be represented in this manner.

In this study the states are the gas generator speed (NG), power turbine/dynamometer speed (NS), and mechanical energy resulting fuel combustion (E). This selection is mandated by the dynamic equations of 3.1, 3.2, and 3.3, one state per derivative term [Ref. 10:p. 665]. The plant

inputs are the fuel flowrate (M_f) and the dynamometer water weight (W_w). Using perturbational variables the state space equation becomes:

$$\begin{Bmatrix} \dot{n}_g \\ \dot{n}_s \\ \dot{e} \end{Bmatrix} = A \begin{Bmatrix} n_g \\ n_s \\ e \end{Bmatrix} + B \begin{Bmatrix} m_f \\ w_w \end{Bmatrix}$$

What remains to be done is to determine the elements of the 'A' and 'B' matrices, which contain the coefficients of the state equation set. We can write these elements symbolically as:

$$\begin{array}{lll} a_{11} = \partial n_g / \partial n_g & a_{12} = \partial n_g / \partial n_s & a_{13} = \partial n_g / \partial e \\ a_{21} = \partial n_s / \partial n_g & a_{22} = \partial n_s / \partial n_s & a_{23} = \partial n_s / \partial e \\ a_{31} = \partial \dot{e} / \partial n_g & a_{32} = \partial \dot{e} / \partial n_s & a_{33} = \partial \dot{e} / \partial e \\ \\ b_{11} = \partial n_g / \partial m_f & b_{12} = \partial n_g / \partial w_w & \\ b_{21} = \partial n_s / \partial m_f & b_{22} = \partial n_s / \partial w_w & \\ b_{31} = \partial \dot{e} / \partial m_f & b_{32} = \partial \dot{e} / \partial w_w & . \end{array}$$

In order to arrive at these coefficients a Taylor series expansion was carried out on each component input/output equation retaining only first order terms. The results is a set of linear equations which can reduced to the state space form given above. A detailed solution for these coefficients is included as Appendix E. It is important to note that these coefficients vary with operating point. A subroutine was added to the steady state program which evaluates these analytic coefficient expressions at user specified operating points (SUBROUTINE PART in Appendix C). Table 5 shows how the 'A' and 'B' matrices vary with operating point.

Comparison between the state space model and nonlinear dynamic model was conducted by subjecting both to the fuel flowrate inputs used in the nonlinear dynamic program validation. Shown in Figure 7.1 and 7.2 is the response of the

TABLE 5

nonlinear and state space models. In this example the 'A' and 'B' matrices were evaluated at the initial condition. As expected for large perturbations such as this, the state space model, with its linear assumptions, does not accurately describe the behavior of this highly nonlinear plant. The limitations of the state space model are important in that they indicate the limits of the LQR controller design and

help to define necessary transitions between linear approximations. When an accurate global dynamic model of the plant is needed for control testing, the nonlinear model will be used.

VIII. CONCLUSIONS AND RECOMMENDATIONS

An accurate nonlinear dynamic computer model of the Naval Postgraduate School marine propulsion test facility has been developed. A state space model has been derived from the nonlinear model.

Prior to controller design the fuel flowrate and dynamometer water weight actuators must be accurately modeled and included in both the nonlinear dynamic program and the state space model. In conjunction with this effort, a new fuel control valve should be installed which will allow more direct control of fuel flowrate. When this is accomplished a new controller should be designed using modern control techniques, specifically the LQR method. Performance tests should then be conducted on the turbine using both the present (classical) controller and the modern controller. These tests should include power level transients as well as simulated sea state conditions.

APPENDIX B
LEAST SQUARES CURVE FIT PROGRAM

```
*****  
***  
** LEAST SQUARES CURVE FIT PROGRAM **  
***  
*****
```

USER INSTRUCTIONS:

THIS PROGRAM OBTAINS A PARABOLIC EQUATION TO FIT THE INDEPENDENT VARIABLE (X^2) TO THE DEPENDENT VARIABLE (B). THE METHOD OF LEAST SQUARES IS USED. THE FORM OF THE PARABOLIC EQUATION IS :

$$C1(XX) + C2(XY) + C3(XZ) + C4(YY) + C5(YZ) + C6(ZZ) \dots \\ + C7(X) + C8(Y) + C9(Z) = B$$

THE OUTPUT OF THIS PROGRAM IS 'C' THE VECTOR OF COEFFICIENTS.
!!!! LOOK CLOSELY AT THE EQUATION FORMAT SO YOU USE THE COEFFICIENTS CORRECTLY!!!!

BEFORE EXECUTING FILE 02 MUST BE DEFINED AND HAVE THE DATA .
THIS IS ACCOMPLISHED BY TYPING :

FILE 2 DISK FILENAME DATA (PERM)
WHERE 'FILENAME' IS THE NAME OF YOUR DATA FILE WHICH HAS
FILETYPE 'DATA' .

CHECK THE READ STATEMENTS TO ENSURE YOU ARE GETTING THE RIGHT
DATA IN THE RIGHT PLACES.
THE INPUT DATA FORMAT SHOULD BE :

| | | | | |
|----|------|----|------|----|
| X1 | Y1 | Z1 | | B1 |
| X2 | Y2 | Z2 | | B2 |
| X3 | | | | |

APPENDIX C
STEADY STATE COMPUTER PROGRAM

\$JOB

```
*****  
**  
** BOEING MODEL 502-6A GAS TURBINE  
**  
** STEADY STATE COMPUTER SIMULATION  
**  
*****
```

USER INSTRUCTIONS:

THIS PROGRAM PROVIDES THE INITIALIZATION PROCESS FOR THE DYNAMIC PROGRAM. SPECIFICALLY THE USER INPUTS GAS GENERATOR AND DYN0 SPEEDS. AND THE PROGRAM USES STEADY STATE MAPS (IN EQUATION FORM) OF SYSTEM INPUTS/OUTPUTS TO FIND STEADY STATE VALUES.

THIS PROGRAM ALSO EVALUATES THE COEFFICIENTS OF THE STATE SPACE MATRICES A AND B AT THE USER SPECIFIED STEADY STATE OPERATING CONDITION.

THE DEVELOPMENT OF THIS COMPUTER SIMULATION IS DESCRIBED IN:

HERDA V.J. 'MARINE GAS TURBINE MODELING
FOR MODERN CONTROL DESIGN' (M.S. THESIS,
NAVAL POSTGRADUATE SCHOOL, MONTEREY, CA.,
JUNE 1986).

GOOD LUCK!!!!

#####

THE FOLLOWING IS A INDEX OF THE PARAMETERS USED IN THIS PROGRAM
A STATE SPACE COEFFICIENT MATRIX.

| | |
|-------|--|
| B | STATE SPACE COEFFICIENT MATRIX. |
| C | VECTOR CONTAINING THE COEFFICIENTS FOR THE QUADRATIC CURVE FIT. |
| MA | AIR FLOW RATE, LBS/HR. |
| MAF | COMBINED FUEL AND AIR FLOW RATE, LBS/HR. |
| MERR | PERCENTAGE ERROR IN FUEL FLOW RATE ALLOWED DURING FUEL FLOW RATE CONVERGENCE. |
| MF | FUEL FLOW RATE, LBS/HR. |
| MFDEL | INCREMENTAL CHANGE IN FUEL FLOW RATE USED WHEN SEARCHING FOR UPPER AND LOWER BOUNDS ON FUEL FLOW RATE. |
| MFL | LOWER LIMIT ON FUEL FLOW RATE. |
| MEMIN | FUEL FLOW RATE WHICH LEADS TO THE MINIMUM GAS GENERATOR TORQUE DIFFERENTIAL. |
| MFU | UPPER LIMIT ON FUEL FLOW RATE. |
| MF1 | INTERMEDIATE FUEL FLOW RATE USED IN FUEL FLOW RATE CONVERGENCE. |
| MF2 | INTERMEDIATE FUEL FLOW RATE USED IN FUEL FLOW RATE CONVERGENCE. |
| NG | GAS GENERATOR SPEED, RPM. |
| NS | DYNAMOMETER SPEED, RPM. |
| PERR | PERCENTAGE ERROR IN PRESSURES (P2,P4) ALLOWED DURING PRESSURE CONVERGENCE. |
| P2 | COMPRESSOR DISCHARGE PRESSURE, PSIA. |
| P2G | GUESS FOR THE COMPRESSOR DISCHARGE PRESSURE, PSIA. |
| P4 | HPT DISCHARGE PRESSURE, PSIA. |
| P4G | GUESS FOR THE HPT DISCHARGE PRESSURE, PSIA. |
| QC | COMPRESSOR TORQUE, FT-LBS. |
| QD | DYNAMOMETER TORQUE, FT-LBS. |

| | |
|--------|--|
| QERR | PERCENTAGE GAS GENERATOR TORQUE DIFFERENTIAL ALLOWED DURING CONVERGENCE. |
| QFPT | FREE POWER TURBINE TORQUE , FT-LBS. |
| QHPT | HIGH PRESSURE TURBINE TORQUE , FT-LBS. |
| QL | QPERC EVALUATED AT MEL. |
| QPERC | PERCENT DIFFERENCE BETWEEN COMPRESSOR AND HIGH PRESSURE TURBINE (HPT) TORQUES. |
| QU | QPERC EVALUATED AT MFU. |
| Q1 | QPERC EVALUATED AT MF1. |
| Q2 | QPERC EVALUATED AT MF2. |
| T2 | COMPRESSOR DISCHARGE TEMPERATURE , DEG. R. |
| T4 | HPT DISCHARGE TEMPERATURE , DEG. R. |
| WW | DYNAMOMETER WATER WEIGHT , LBS. |
| WWERR | PERCENTAGE ERROR IN DYNOMETER WATER WEIGHT ALLOWED DURING WATER WEIGHT CONVERGENCE. |
| X | VECTOR CONTAINING THE SCALED INPUTS AND OUTPUTS. |
| XCOUNT | COUNTER USED DURING ESTABLISHMENT OF FUEL FLOW RATE BOUNDS. |
| XK | COUNTER ON THE NUMBER OF FUNCTION EVALUATIONS DURING THE GOLDEN SECTION METHOD. |
| XN | NUMBER OF FUNCTION EVALUATIONS NEEDED FOR MF TO CONVERGE WITHIN MERR DURING GOLDEN SECTION METHOD ITERATION. |
| XR | VECTOR CONTAINING THE UNSCALED INPUTS AND OUTPUTS. |
| Z | VECTOR CONTAINING THE SCALING FACTORS FOR THE VARIOUS INPUTS AND OUTPUTS. |

APPENDIX D
NONLINEAR DYNAMIC PROGRAM

TITLE GT DYNAMIC PROGRAM

```
*****  
**  
** BOEING MODEL 502-6A GAS TURBINE  
**  
** DYNAMIC COMPUTER SIMULATION  
*****
```

THIS PROGRAM SIMULATES THE DYNAMIC RESPONSE OF THE NPS BOEING GAS TURBINE PROPULSION TEST FACILITY USING A NONLINEAR SIMULATION AND A LINEAR (STATE SPACE) SIMULATION.

THE DEVELOPMENT OF THIS COMPUTER SIMULATION IS DESCRIBED IN:

HIERDA V. J. 'MARINE GAS TURBINE MODELING FOR MODERN CONTROL DESIGN' (M.S. THESIS, NAVAL POSTGRADUATE SCHOOL, MONTEREY, CA., JUNE 1986).

GOOD LUCK!!!!

#####

PARAM JG=0, 009525, JD=0, 6738, PI=3, 14159, T = 2.00

THE FOLLOWING VALUES LISTED ON THE FUNCTION CARD ARE FOR FUEL FLOW, GAS GENERATOR SPEED AND DYN0 SPEED AS A FUNCTION OF TIME. THESE VALUES WERE OBTAINED FROM STRIP CHART RECORDS AND ARE ENTERED IN THE FORM (E.G. FUEL FLOW) ... TIME(SEC), FUEL FLOW

THIS SET IS FOR EXPERIMENTAL RUN # 1.

AFGEN MFDATA = 0, 0, 104, 3, .05, 104, 3, . . .

APPENDIX E
STATE EQUATION FORMULATION

1. Note that for any variable Y,

$$Y = Y_0 + \Delta Y$$

where $Y.$ = final value

Y_0 = initial value

ΔY = change in Y

Assume the initial condition, Y_0 , is known. Then the final state, Y, can be found if ΔY is known.

Applying a Taylor series approximation to Y, where Y is a function of X (i.e. $Y = Y(X)$) yields,

$$Y - Y_0 = \Delta Y = Y_0 + Y_0'(\Delta X) + Y_0''(\Delta X)^2/2! + \dots + Y_{n-1}(\Delta X)^{n-1}/(n-1)! + Y_n(\Delta X)^n/n!$$

For very small changes in X, a linear approximation can be made:

$$Y = dY = Y_0 + Y_0 * dX.$$

As a convenience of notation the following substitution is made:

$$dY = y$$

2. If Y is a function of X (i.e. $Y = Y(X)$), then (making the linear assumption)

$$\partial Y / \partial X = \partial Y_0 / \partial X + \partial y / \partial X.$$

But $\partial Y_0 / \partial X = 0$, since Y_0 is a constant.
Then in general,

$$\partial Y / \partial X = \partial y / \partial X.$$

3. In what follows the state space equation set for the propulsion test facility is derived by using a linear Taylor series approximation for each of the input/output equations used in the nonlinear model.
